

INTRODUCTION: FURTHER APPLICATIONS OF NEWTON'S LAWS

Figure 1: Total hip replacement surgery has become a common procedure. The head (or ball) of the patient's femur fits into a cup that has a hard plastic-like inner lining. (credit: National Institutes of Health, via Wikimedia Commons)

Describe the forces on the hip joint. What means are taken to ensure that this will be a good movable joint? From the photograph (for an adult) in [Figure 1](#), estimate the dimensions of the artificial device.

It is difficult to categorize forces into various types (aside from the four basic forces discussed in previous chapter). We know that a net force affects the motion, position, and shape of an object. It is useful at this point to look at some particularly interesting and common forces that will provide further applications of Newton's laws of motion. We have in mind the forces of friction, air or liquid drag, and deformation.

$f = G \frac{m_1 m_2}{r^2}$

Under an assumption of constant gravity, Newton's law of universal gravitation simplifies to $F = mg$, where m is the mass of the body and g is a direction vector with an average magnitude of 9.80 m/s^2 .

The force of gravity is given by the equation:
 $F_g = mg$
where: F_g = force of gravity [N]
 m = mass [kg]
 g = gravitational acceleration [m/s^2]
"g" has the famous value of 9.80 m/s^2 near the surface of the earth
