

Introduction to Science and the Realm of Physics, Physical Quantities, and Units

Galaxies are as immense as atoms are small. Yet the same laws of physics describe both, and all the rest of nature—an indication of the underlying unity in the universe. The laws of physics are surprisingly few in number, implying an underlying simplicity to nature’s apparent complexity. (credit: NASA, JPL-Caltech, P. Barmby, Harvard-Smithsonian Center for Astrophysics)

What is your first reaction when you hear the word “physics”? Did you imagine working through difficult equations or memorizing formulas that seem to have no real use in life outside the physics classroom? Many people come to the subject of physics with a bit of fear. But as you begin your exploration of this broad-ranging subject, you may soon come to realize that physics plays a much larger role in your life than you first thought, no matter your life goals or career choice.

For example, take a look at the image above. This image is of the Andromeda Galaxy, which contains billions of individual stars, huge clouds of gas, and dust. Two smaller galaxies are also visible as bright blue spots in the background. At a staggering 2.5 million light years from the Earth, this galaxy is the nearest one to our own galaxy (which is called the Milky Way). The stars and planets that make up Andromeda might seem to be the furthest thing from most people’s regular, everyday lives. But Andromeda is a great starting point to think about the forces that hold together the universe. The forces that cause Andromeda to act as it does are the same forces we contend with here on Earth, whether we are planning to send a rocket into space or simply raise the walls for a new home. The same gravity that causes the stars of Andromeda to rotate and revolve also causes water to flow over hydroelectric dams here on Earth. Tonight, take a moment to look up at the stars. The forces out there are the same as the ones here on Earth. Through a study of physics, you may gain a greater understanding of the interconnectedness of everything we can see and know in this universe.

Humans have created and manufactured millions of different objects over the history of our species. Successive technological periods (often referred to as the Stone Age, the Bronze Age, the Iron Age, and so on) were marked by our knowledge of the physical properties of certain materials and our ability to manipulate them. This knowledge all stems from physics, whether it’s the way a rock would flake when constructing a spear point, the effect of integrating carbon with iron in South Indian and Sri Lankan furnaces to create the earliest high-quality steel, or the proper way to combine perfectly ground and polished pieces of glass to create optical instruments. Our current technological age, the Information Age, builds on all that knowledge and can be traced to critical innovations made by people from all backgrounds working together. Mohamed M. Atalla and Dawon Kahng, for example, invented the **MOSFET** (metal-oxide-semiconductor field-effect transistor). Although unknown to most people, this tiny device, created in 1959 by an Egyptian-born scientist and Korean-born scientist working in a lab in New Jersey, is the basis for modern electronics. More MOSFETs have been produced than any other object in human history. They are used in computers, smartphones, microwave ovens, automotive controls, medical instruments, and nearly every other electronic device.

Next, think about the most exciting modern technologies that you have heard about in the news, such as trains that levitate above tracks, “invisibility cloaks” that bend light around them, and microscopic robots that fight cancer cells in our bodies. All of these groundbreaking advancements, commonplace or unbelievable, rely on the principles of physics. Aside from playing a significant role in technology, professionals such as engineers, pilots, physicians, physical therapists, electricians, and computer programmers apply physics concepts in their daily work. For example, a pilot must understand how wind forces affect a flight path and a physical therapist must understand how the muscles in the body experience forces as they move and bend. As you will learn in this text, physics principles are propelling new, exciting technologies, and these principles are applied in a wide range of careers.

In this text, you will begin to explore the history of the formal study of physics, beginning with natural philosophy and the ancient Greeks, and leading up through a review of Sir Isaac Newton and the laws of physics that bear his name. You will also be introduced to the standards scientists use when they study physical quantities and the interrelated system of measurements most of the scientific community uses to communicate in a single mathematical language. Finally, you will study the limits of our ability to be accurate and precise, and the reasons scientists go to painstaking lengths to be as clear as possible regarding their own limitations.

Physics: An Introduction

- Explain the difference between a principle and a law.
- Explain the difference between a model and a theory.

The flight formations of migratory birds such as Canada geese are governed by the laws of physics. (credit: David Merrett)

The physical universe is enormously complex in its detail. Every day, each of us observes a great variety of objects and phenomena. Over the centuries, the curiosity of the human race has led us collectively to explore and catalog a tremendous wealth of information. From the flight of birds to the colors of flowers, from lightning to gravity, from quarks to clusters of galaxies, from the flow of time to the mystery of the creation of the universe, we have asked questions and assembled huge arrays of facts. In the face of all these details, we have discovered that a surprisingly small and unified set of physical laws can explain what we observe. As humans, we make generalizations and seek order. We have found that nature is remarkably cooperative—it exhibits the **underlying order and simplicity** we so value.

It is the underlying order of nature that makes science in general, and physics in particular, so enjoyable to study. For example, what do a bag of chips and a car battery have in common? Both contain energy that can be converted to other forms. The law of conservation of energy (which says that energy can change form but is never lost) ties together such topics as food calories, batteries, heat, light, and watch springs. Understanding this law makes it easier to learn about the various forms energy takes and how they relate to one another. Apparently unrelated topics are connected through broadly applicable physical laws, permitting an understanding beyond just the memorization of lists of facts.

The unifying aspect of physical laws and the basic simplicity of nature form the underlying themes of this text. In learning to apply these laws, you will, of course, study the most important topics in physics. More importantly, you will gain analytical abilities that will enable you to apply these laws far beyond the scope of what can be included in a single book. These analytical skills will help you to excel academically, and they will also help you to think critically in any professional career you choose to pursue. This module discusses the realm of physics (to define what physics is), some applications of physics (to illustrate its relevance to other disciplines), and more precisely what constitutes a physical law (to illuminate the importance of experimentation to theory).

Science and the Realm of Physics

Science consists of the theories and laws that are the general truths of nature as well as the body of knowledge they encompass. Scientists are continually trying to expand this body of knowledge and to perfect the expression of the laws that describe it. **Physics** is concerned with describing the interactions of energy, matter, space, and time, and it is especially interested in what fundamental mechanisms underlie every phenomenon. The concern for describing the basic phenomena in nature essentially defines the **realm of physics**.

Physics aims to describe the function of everything around us, from the movement of tiny charged particles to the motion of people, cars, and spaceships. In fact, almost everything around you can be described quite accurately by the laws of physics. Consider a smartphone ([Figure 2](#)). Physics describes how electricity interacts with the various circuits inside the device. This knowledge helps engineers select the appropriate materials and circuit layout when building the smartphone. Next, consider a GPS system. Physics describes the relationship between the speed of an object, the distance over which it travels, and the time it takes to travel that distance. GPS relies on precise calculations that account for variations in the Earth's landscapes, the exact distance between orbiting satellites, and even the effect of a complex occurrence of time dilation. Most of these calculations are founded on algorithms developed by Gladys West, a mathematician and computer scientist who programmed the first computers capable of highly accurate remote sensing and positioning. When you use a GPS device, it utilizes these algorithms to recognize where you are and how your position relates to other objects on Earth.

The Apple “iPhone” is a common smartphone with a GPS function. Physics describes the way that electricity flows through the circuits of this device. Engineers use their knowledge of physics to construct an iPhone with features that consumers will enjoy. One specific feature of an iPhone is the GPS function. GPS uses physics equations to determine the driving time between two locations on a map. (credit: Tinh tế Photo/Flickr)

Applications of Physics

You need not be a scientist to use physics. On the contrary, knowledge of physics is useful in everyday situations as well as in nonscientific professions. It can help you understand how microwave ovens work, why metals should not be put into them, and why they might affect pacemakers. (See [Figure 3](#) and [Figure 4](#).) Physics allows you to understand the hazards of radiation and rationally evaluate these hazards more easily. Physics also explains the reason why a black car radiator helps remove heat in a car engine, and it explains why a white roof helps keep the inside of a house cool. Similarly, the operation of a car’s ignition system as well as the transmission of electrical signals through our body’s nervous system are much easier to understand when you think about them in terms of basic physics.

Physics is the foundation of many important disciplines and contributes directly to others. Chemistry, for example—since it deals with the interactions of atoms and molecules—is rooted in atomic and molecular physics. Most branches of engineering are applied physics. In architecture, physics is at the heart of structural stability, and is involved in the acoustics, heating, lighting, and cooling of buildings. Parts of geology rely heavily on physics, such as radioactive dating of rocks, earthquake analysis, and heat transfer in the Earth. Some disciplines, such as biophysics and geophysics, are hybrids of physics and other disciplines.

Physics has many applications in the biological sciences. On the microscopic level, it helps describe the properties of cell walls and cell membranes ([Figure 5](#) and [Figure 6](#)). On the macroscopic level, it can explain the heat, work, and power associated with the human body. Physics is involved in medical diagnostics, such as X-rays, magnetic resonance imaging (MRI), and ultrasonic blood flow measurements. Medical therapy sometimes directly involves physics; for example, cancer radiotherapy uses ionizing radiation. Physics can also explain sensory phenomena, such as how musical instruments make sound, how the eye detects color, and how lasers can transmit information.

It is not necessary to formally study all applications of physics. What is most useful is knowledge of the basic laws of physics and a skill in the analytical methods for applying them. The study of physics also can improve your problem-solving skills. Furthermore, physics has retained the most basic aspects of science, so it is used by all of the sciences, and the study of physics makes other sciences easier to understand.

The laws of physics help us understand how common appliances work. For example, the laws of physics can help explain how microwave ovens heat up food, and they also help us understand why it is dangerous to place metal objects in a microwave oven. (credit: MoneyBlogNewz)

These two applications of physics have more in common than meets the eye. Microwave ovens use electromagnetic waves to heat food. Magnetic resonance imaging (MRI) also uses electromagnetic waves to yield an image of the brain, from which the exact location of tumors can be determined. (credit: Rashmi Chawla, Daniel Smith, and Paul E. Marik)

Physics, chemistry, and biology help describe the properties of cell walls in plant cells, such as the onion cells seen here. (credit: Umberto Salvagnin)

An artist's rendition of the structure of a cell membrane. Membranes form the boundaries of animal cells and are complex in structure and function. Many of the most fundamental properties of life, such as the firing of nerve cells, are related to membranes. The disciplines of biology, chemistry, and physics all help us understand the membranes of animal cells. (credit: Mariana Ruiz)

Models, Theories, and Laws; The Role of Experimentation

The laws of nature are concise descriptions of the universe around us; they are human statements of the underlying laws or rules that all natural processes follow. Such laws are intrinsic to the universe; humans did not create them and so cannot change them. We can only discover and understand them. Their discovery is a very human endeavor, with all the elements of mystery, imagination, struggle, triumph, and disappointment inherent in any creative effort. (See [Figure 7](#) and [Figure 8](#).) The cornerstone of discovering natural laws is observation; science must describe the universe as it is, not as we may imagine it to be.

Sir Isaac Newton

Isaac Newton (1642–1727) was very reluctant to publish his revolutionary work and had to be convinced to do so. In his later years, he stepped down from his academic post and became exchequer of the Royal Mint. He took this post seriously, inventing reeding (or creating ridges) on the edge of coins to prevent unscrupulous people from trimming the silver off of them before using them as currency. (credit: Arthur Shuster and Arthur E. Shipley: Britain's Heritage of Science. London, 1917.)

Marie Curie (1867–1934) sacrificed monetary assets to help finance her early research and damaged her physical well-being with radiation exposure. She is the only person to win Nobel prizes in both physics and chemistry. One of her daughters also won a Nobel Prize. (credit: Wikimedia Commons)

We all are curious to some extent. We look around, make generalizations, and try to understand what we see—for example, we look up and wonder whether one type of cloud signals an oncoming storm. As we become serious about exploring nature, we become more organized and formal in collecting and analyzing data. We attempt greater precision, perform controlled experiments (if we can), and write down ideas about how the data may be organized and unified. We then formulate models, theories, and laws based on the data we have collected and analyzed to generalize and communicate the results of these experiments.

A **model** is a representation of something that is often too difficult (or impossible) to display directly. While a model is justified with experimental proof, it is only accurate under limited situations. An example is the planetary model of the atom in which electrons are pictured as orbiting the nucleus, analogous to the way planets orbit the Sun. (See [Figure 9.](#)) We cannot observe electron orbits directly, but the mental image helps explain the observations we can make, such as the emission of light from hot gases (atomic spectra). Physicists use models for a variety of purposes. For example, models can help physicists analyze a scenario and perform a calculation, or they can be used to represent a situation in the form of a computer simulation. A **theory** is an explanation for patterns in nature that is supported by scientific evidence and verified multiple times by various groups of researchers. Some theories include models to help visualize phenomena, whereas others do not. Newton’s theory of gravity, for example, does not require a model or mental image, because we can observe the objects directly with our own senses. The kinetic theory of gases, on the other hand, is a model in which a gas is viewed as being composed of atoms and molecules. Atoms and molecules are too small to be observed directly with our senses—thus, we picture them mentally to understand what our instruments tell us about the behavior of gases.

A **law** uses concise language to describe a generalized pattern in nature that is supported by scientific evidence and repeated experiments. Often, a law can be expressed in the form of a single mathematical equation. Laws and theories are similar in that they are both scientific statements that result from a tested hypothesis and are supported by scientific evidence. However, the designation **law** is reserved for a concise and very general statement that describes phenomena in nature, such as the law that energy is conserved during any process, or Newton’s second law of motion, which relates force, mass, and acceleration by the simple equation $\vec{F} = m\vec{a}$. A theory, in contrast, is a less concise statement of observed phenomena. For example, the Theory of Evolution and the Theory of Relativity cannot be expressed concisely enough to be considered a law. The biggest difference between a law and a theory is that a theory is much more complex and dynamic. A law describes a single action, whereas a theory explains an entire group of related phenomena. And, whereas a law is a postulate that forms the foundation of the scientific method, a theory is the end result of that process.

Less broadly applicable statements are usually called principles (such as Pascal’s principle, which is applicable only in fluids), but the distinction between laws and principles often is not carefully made.

What is a model? This planetary model of the atom shows electrons orbiting the nucleus. It is a drawing that we use to form a mental image of the atom that we cannot see directly with our eyes because it is too small.

Models, Theories, and Laws

Models, theories, and laws are used to help scientists analyze the data they have already collected. However, often after a model, theory, or law has been developed, it points scientists toward new discoveries they would not otherwise have made.

The models, theories, and laws we devise sometimes *imply the existence of objects or phenomena as yet unobserved*. These predictions are remarkable triumphs and tributes to the power of science. It is the underlying order in the universe that enables scientists to make such spectacular predictions. However, if **experiment** does not verify our predictions, then the theory or law is wrong, no matter how elegant or convenient it is. Laws can never be known with absolute certainty because it is impossible to perform every imaginable experiment in order to confirm a law in every possible scenario. Physicists operate under the assumption that all scientific laws and theories are valid until a counterexample is observed. If a good-quality, verifiable experiment contradicts a well-established law, then the law must be modified or overthrown completely.

The study of science in general and physics in particular is an adventure much like the exploration of uncharted ocean. Discoveries are made; models, theories, and laws are formulated; and the beauty of the physical universe is made more sublime for the insights gained.

The Scientific Method

Ibn al-Haytham (sometimes referred to as Alhazen), a 10th-11th century scientist working in Cairo, significantly advanced the understanding of optics and vision. But his contributions go much further. In demonstrating that previous approaches were incorrect, he emphasized that scientists must be ready to reject existing knowledge and become “the enemy” of everything they read; he expressed that scientists must trust only objective evidence. Al-Haytham emphasized repeated experimentation and validation, and acknowledged that senses and predisposition could lead to poor conclusions. His work was a precursor to the scientific method that we use today.

As scientists inquire and gather information about the world, they follow a process called the **scientific method**. This process typically begins with an observation and question that the scientist will research. Next, the scientist typically performs some research about the topic and then devises a hypothesis. Then, the scientist will test the hypothesis by performing an experiment. Finally, the scientist analyzes the results of the experiment and draws a conclusion. Note that the scientific method can be applied to many situations that are not limited to science, and this method can be modified to suit the situation.

Consider an example. Let us say that you try to turn on your car, but it will not start. You undoubtedly wonder: Why will the car not start? You can follow a scientific method to answer this question. First off, you may perform some research to determine a variety of reasons why the car will not start. Next, you will state a hypothesis. For example, you may believe that the car is not starting because it has no engine oil. To test this, you open the hood of the car and examine the oil level. You observe that the oil is at an acceptable level, and you thus conclude that the oil level is not contributing to your car issue. To troubleshoot the issue further, you may devise a new hypothesis to test and then repeat the process again.

The Evolution of Natural Philosophy into Modern Physics

Physics was not always a separate and distinct discipline. It remains connected to other sciences to this day. The word **physics** comes from Greek, meaning nature. The study of nature came to be called “natural philosophy.” From ancient times through the Renaissance, natural philosophy encompassed many fields, including astronomy, biology, chemistry, physics, mathematics, and medicine. Over the last few centuries, the growth of

knowledge has resulted in ever-increasing specialization and branching of natural philosophy into separate fields, with physics retaining the most basic facets. (See [Figure 10](#), [Figure 11](#), and [Figure 12](#).) Physics as it developed from the Renaissance to the end of the 19th century is called **classical physics**. It was transformed into modern physics by revolutionary discoveries made starting at the beginning of the 20th century.

Over the centuries, natural philosophy has evolved into more specialized disciplines, as illustrated by the contributions of some of the greatest minds in history. The Greek philosopher Aristotle (384–322 B.C.) wrote on a broad range of topics including physics, animals, the soul, politics, and poetry. (credit: Jastrow (2006)/Ludovisi Collection)

Galileo Galilei (1564–1642) laid the foundation of modern experimentation and made contributions in mathematics, physics, and astronomy. (credit: Domenico Tintoretto)

Niels Bohr (1885–1962) made fundamental contributions to the development of quantum mechanics, one part of modern physics. (credit: United States Library of Congress Prints and Photographs Division)

Classical physics is not an exact description of the universe, but it is an excellent approximation under the following conditions: Matter must be moving at speeds less than about 1% of the speed of light, the objects dealt with must be large enough to be seen with a microscope, and only weak gravitational fields, such as the field generated by the Earth, can be involved. Because humans live under such circumstances, classical physics seems intuitively reasonable, while many aspects of modern physics seem bizarre. This is why models are so useful in modern physics—they let us conceptualize phenomena we do not ordinarily experience. We can relate to models in human terms and visualize what happens when objects move at high speeds or imagine what objects too small to observe with our senses might be like. For example, we can understand an atom's properties because we can picture it in our minds, although we have never seen an atom with our eyes. New tools, of course, allow us to better picture phenomena we cannot see. In fact, new instrumentation has allowed us in recent years to actually “picture” the atom. (see [Figure 13.](#))

Limits on the Laws of Classical Physics

For the laws of classical physics to apply, the following criteria must be met: Matter must be moving at speeds less than about 1% of the speed of light, the objects dealt with must be large enough to be seen with a microscope, and only weak gravitational fields (such as the field generated by the Earth) can be involved.

Using a scanning tunneling microscope (STM), scientists can see the individual atoms that compose this sheet of gold. (credit: Erwinrossen)

Some of the most spectacular advances in science have been made in modern physics. Many of the laws of classical physics have been modified or rejected, and revolutionary changes in technology, society, and our view of the universe have resulted. Like science fiction, modern physics is filled with fascinating objects beyond our normal experiences, but it has the advantage over science fiction of being very real. Why, then, is the majority of this text devoted to topics of classical physics? There are two main reasons: Classical physics gives an extremely accurate description of the universe under a wide range of everyday circumstances, and knowledge of classical physics is necessary to understand modern physics.

Modern physics itself consists of the two revolutionary theories, relativity and quantum mechanics. These theories deal with the very fast and the very small, respectively. **Relativity** must be used whenever an object is traveling at greater than about 1% of the speed of light or experiences a strong gravitational field such as that near the Sun. **Quantum mechanics** must be used for objects smaller than can be seen with a microscope. The combination of these two theories is *relativistic quantum mechanics*, and it describes the behavior of small objects traveling at high speeds or experiencing a strong gravitational field. Relativistic quantum mechanics is the best universally applicable theory we have. Because of its mathematical complexity, it is used

only when necessary, and the other theories are used whenever they will produce sufficiently accurate results. We will find, however, that we can do a great deal of modern physics with the algebra and trigonometry used in this text.

Check Your Understanding

A friend tells you he has learned about a new law of nature. What can you know about the information even before your friend describes the law? How would the information be different if your friend told you he had learned about a scientific theory rather than a law?

Show Solution

Without knowing the details of the law, you can still infer that the information your friend has learned conforms to the requirements of all laws of nature: it will be a concise description of the universe around us; a statement of the underlying rules that all natural processes follow. If the information had been a theory, you would be able to infer that the information will be a large-scale, broadly applicable generalization.

Graphing Quadratics

Learn about graphing polynomials. The shape of the curve changes as the constants are adjusted. View the curves for the individual terms (e.g. $y = bx$) to see how they add to generate the polynomial curve.

Graphing Quadratics

Summary

- Science seeks to discover and describe the underlying order and simplicity in nature.
- Physics is the most basic of the sciences, concerning itself with energy, matter, space and time, and their interactions.
- Scientific laws and theories express the general truths of nature and the body of knowledge they encompass. These laws of nature are rules that all natural processes appear to follow.

Conceptual Questions

Models are particularly useful in relativity and quantum mechanics, where conditions are outside those normally encountered by humans. What is a model?

How does a model differ from a theory?

If two different theories describe experimental observations equally well, can one be said to be more valid than the other (assuming both use accepted rules of logic)?

What determines the validity of a theory?

Certain criteria must be satisfied if a measurement or observation is to be believed. Will the criteria necessarily be as strict for an expected result as for an unexpected result?

Can the validity of a model be limited, or must it be universally valid? How does this compare to the required validity of a theory or a law?

Classical physics is a good approximation to modern physics under certain circumstances. What are they?

When is it **necessary** to use relativistic quantum mechanics?

Can classical physics be used to accurately describe a satellite moving at a speed of 7500 m/s? Explain why or why not.

Glossary

classical physics

physics that was developed from the Renaissance to the end of the 19th century

physics

the science concerned with describing the interactions of energy, matter, space, and time; it is especially interested in what fundamental mechanisms underlie every phenomenon

model

representation of something that is often too difficult (or impossible) to display directly

theory

an explanation for patterns in nature that is supported by scientific evidence and verified multiple times by various groups of researchers

law

a description, using concise language or a mathematical formula, a generalized pattern in nature that is supported by scientific evidence and repeated experiments

scientific method

a method that typically begins with an observation and question that the scientist will research; next, the scientist typically performs some research about the topic and then devises a hypothesis; then, the scientist will test the hypothesis by performing an experiment; finally, the scientist analyzes the results of the experiment and draws a conclusion

modern physics

the study of relativity, quantum mechanics, or both

relativity

the study of objects moving at speeds greater than about 1% of the speed of light, or of objects being affected by a strong gravitational field

quantum mechanics

the study of objects smaller than can be seen with a microscope

This work is licensed under a [Creative Commons Attribution 4.0 International License](https://creativecommons.org/licenses/by/4.0/).

Physical Quantities and Units

- Perform unit conversions both in the SI and English units.
- Explain the most common prefixes in the SI units and be able to write them in scientific notation.

The distance from Earth to the Moon may seem immense, but it is just a tiny fraction of the distances from Earth to other celestial bodies.
(credit: NASA)

The range of objects and phenomena studied in physics is immense. From the incredibly short lifetime of a nucleus to the age of the Earth, from the tiny sizes of sub-nuclear particles to the vast distance to the edges of the known universe, from the force exerted by a jumping flea to the force between Earth and the Sun, there are enough factors of 10 to challenge the imagination of even the most experienced scientist. Giving numerical values for physical quantities and equations for physical principles allows us to understand nature much more deeply than does qualitative description alone. To comprehend these vast ranges, we must also have accepted units in which to express them. And we shall find that (even in the potentially mundane discussion of meters, kilograms, and seconds) a profound simplicity of nature appears—all physical quantities can be expressed as combinations of only four fundamental physical quantities: length, mass, time, and electric current.

We define a **physical quantity** either by *specifying how it is measured* or by **stating how it is calculated** from other measurements. For example, we define distance and time by specifying methods for measuring them, whereas we define **average speed** by stating that it is calculated as distance traveled divided by time of travel.

Measurements of physical quantities are expressed in terms of **units**, which are standardized values. For example, the length of a race, which is a physical quantity, can be expressed in units of meters (for sprinters) or kilometers (for distance runners). Without standardized units, it would be extremely difficult for scientists to express and compare measured values in a meaningful way. (See [Figure 2.](#))

Distances given in unknown units are maddeningly useless.

There are two major systems of units used in the world: **SI units** (also known as the metric system) and **English units** (also known as the customary or imperial system). **English units** were historically used in nations once ruled by the British Empire and are still widely used in the United States. Virtually every other country in the world now uses SI units as the standard; the metric system is also the standard system agreed upon by scientists and mathematicians. The acronym “SI” is derived from the French *Système International*.

SI Units: Fundamental and Derived Units

[Table 1](#) gives the fundamental SI units that are used throughout this textbook. This text uses non-SI units in a few applications where they are in very common use, such as the measurement of blood pressure in millimeters of mercury (mm Hg). Whenever non-SI units are discussed, they will be tied to SI units through conversions.

Table 1: Fundamental SI Units

Length	Mass	Time	Electric Current
meter (m)	kilogram (kg)	second (s)	ampere (A)

It is an intriguing fact that some physical quantities are more fundamental than others and that the most fundamental physical quantities can be defined **only** in terms of the procedure used to measure them. The units in which they are measured are thus called **fundamental units**. In this textbook, the fundamental physical quantities are taken to be length, mass, time, and electric current. (Note that electric current will not be introduced until much later in this text.) All other physical quantities, such as force and electric charge, can be expressed as algebraic combinations of length, mass, time, and current (for example, speed is length divided by time); these units are called **derived units**.

Units of Time, Length, and Mass: The Second, Meter, and Kilogram

The Second

The SI unit for time, the **second** (abbreviated s), has a long history. For many years it was defined as $1/86\,400$ of a mean solar day. More recently, a new standard was adopted to gain greater accuracy and to define the second in terms of a non-varying, or constant, physical phenomenon (because the solar day is getting longer due to very gradual slowing of the Earth's rotation). Cesium atoms can be made to vibrate in a very steady way, and these vibrations can be readily observed and counted. In 1967 the second was redefined as the time required for 9 192 631 770 of these vibrations. (See [Figure 3.](#)) Accuracy in the fundamental units is essential, because all measurements are ultimately expressed in terms of fundamental units and can be no more accurate than are the fundamental units themselves.

An atomic clock such as this one uses the vibrations of cesium atoms to keep time to a precision of better than a microsecond per year. The fundamental unit of time, the second, is based on such clocks. This image is looking down from the top of an atomic fountain nearly 30 feet tall! (credit: Steve Jurvetson/Flickr)

The Meter

The SI unit for length is the **meter** (abbreviated m); its definition has also changed over time to become more accurate and precise. The meter was first defined in 1791 as $1/10\,000\,000$ of the distance from the equator to the North Pole. This measurement was improved in 1889 by redefining the meter to be the distance between two engraved lines on a platinum-iridium bar now kept near Paris. By 1960, it had become possible to define the meter even more accurately in terms of the wavelength of light, so it was again redefined as 1 650 763.73 wavelengths of orange light emitted by krypton atoms. In 1983, the meter was given its present definition (partly for greater accuracy) as the distance light travels in a vacuum in $1/299\,792\,458$ of a second. (See [Figure 4.](#)) This change defines the speed of light to be exactly 299 792 458 meters per second. The length of the meter will change if the speed of light is someday measured with greater accuracy.

The Kilogram

The SI unit for mass is the **kilogram** (abbreviated kg); it was previously defined to be the mass of a platinum-iridium cylinder kept with the old meter standard at the International Bureau of Weights and Measures near Paris. Exact replicas of the previously defined kilogram are also kept at the United States' National Institute of Standards and Technology, or NIST, located in Gaithersburg, Maryland outside of Washington D.C., and at other locations around the world. The determination of all other masses could be ultimately traced to a comparison with the standard mass. Even though the platinum-iridium cylinder was resistant to corrosion, airborne contaminants were able to adhere to its surface, slightly changing its mass over time. In May 2019, the scientific community adopted a more stable definition of the kilogram. The kilogram is now defined in terms of the second, the meter, and Planck's constant, h (a quantum mechanical value that relates a photon's energy to its frequency).

The meter is defined to be the distance light travels in $1/299\,792\,458$ of a second in a vacuum. Distance traveled is speed multiplied by time.

Electric current and its accompanying unit, the ampere, will be introduced in later units when electricity and magnetism are covered. The initial modules in this textbook are concerned with mechanics. In this subject all pertinent physical quantities can be expressed in terms of the fundamental units of length, mass, and time.

Metric Prefixes

SI units are part of the **metric system**. The metric system is convenient for scientific and engineering calculations because the units are categorized by factors of 10. [Table 2](#) gives metric prefixes and symbols used to denote various factors of 10.

Metric systems have the advantage that conversions of units involve only powers of 10. There are 100 centimeters in a meter, 1000 meters in a kilometer, and so on. In nonmetric systems, such as the system of U.S. customary units, the relationships are not as simple—there are 12 inches in a foot, 5280 feet in a mile, and so on. Another advantage of the metric system is that the same unit can be used over extremely large ranges of values simply by using an appropriate metric prefix. For example, distances in meters are suitable in construction, while distances in kilometers are appropriate for air travel, and the tiny measure of nanometers are convenient in optical design. With the metric system there is no need to invent new units for particular applications.

The term **order of magnitude** refers to the scale of a value expressed in the metric system. Each power of 10 in the metric system represents a different order of magnitude. For example, 10^1 , 10^2 , 10^3 , and so forth are all different orders of magnitude. All quantities that can be expressed as a product of a specific power of 10 are said to be of the **same** order of magnitude. For example, the number 800 can be written as 8×10^2 , and the number 450 can be written as 4.5×10^2 . Thus, the numbers 800 and 450 are of the same order of magnitude: 10^2 . Order of magnitude can be thought of as a ballpark estimate for the scale of a value. The diameter of an atom is on the order of 10^{-9} m, while the diameter of the Sun is on the order of 10^9 m.

The Quest for Microscopic Standards for Basic Units

The fundamental units described in this chapter are those that produce the greatest accuracy and precision in measurement. There is a sense among physicists that, because there is an underlying microscopic substructure to matter, it would be most satisfying to base our standards of measurement on microscopic objects and fundamental physical phenomena such as the speed of light. A microscopic standard has been accomplished for the standard of time, which is based on the oscillations of the cesium atom.

The standard for length was once based on the wavelength of light (a small-scale length) emitted by a certain type of atom, but it has been supplanted by the more precise measurement of the speed of light. If it becomes possible to measure the mass of atoms or a particular arrangement of atoms such as a silicon sphere to greater precision than the kilogram standard, it may become possible to base mass measurements on the small scale. There are also possibilities that electrical phenomena on the small scale may someday allow us to base a unit of charge on the charge of electrons and protons, but at present current and charge are related to large-scale currents and forces between wires.

 **Table 2: Metric Prefixes for Powers of 10 and their Symbols**

Prefix	Symbol	Value	Example	Example (some are approximate)
exa	E	10^{18}	exameter Em	10^{18} m distance light travels in a century
peta	P	10^{15}	petasecond Ps	10^{15} s 30 million years
tera	T	10^{12}	terawatt TW	10^{12} W powerful laser output
giga	G	10^9	gigahertz GHz	10^9 Hz a microwave frequency
mega	M	10^6	megacurie MCi	10^6 Ci high radioactivity
kilo	k	10^3	kilometer km	10^3 m about 6/10 mile
hecto	h	10^2	hectoliter hL	10^2 L 26 gallons
deka	da	10^1	dekagram dag	10^1 g teaspoon of butter
—	—	10^0	(=1)	
deci	d	10^{-1}	deciliter dL	10^{-1} L less than half a soda
centi	c	10^{-2}	centimeter cm	10^{-2} m fingertip thickness
milli	m	10^{-3}	millimeter mm	10^{-3} m flea at its shoulders
micro	μ	10^{-6}	micrometer μ m	10^{-6} m detail in microscope
nano	n	10^{-9}	nanogram ng	10^{-9} g small speck of dust
pico	p	10^{-12}	picofarad pF	10^{-12} F small capacitor in radio
femto	f	10^{-15}	femtometer fm	10^{-15} m size of a proton
atto	a	10^{-18}	attosecond as	10^{-18} s time light crosses an atom

Known Ranges of Length, Mass, and Time

The vastness of the universe and the breadth over which physics applies are illustrated by the wide range of examples of known lengths, masses, and times in [Table 3](#). Examination of this table will give you some feeling for the range of possible topics and numerical values. (See [Figure 5](#) and [Figure 6](#).)

!A magnified image of tiny phytoplankton swimming among the crystal of ice.

Galaxies collide 2.4 billion light years away from Earth. The tremendous range of observable phenomena in nature challenges the imagination. (credit: NASA/CXC/UVic./A. Mahdavi et al. Optical/lensing: CFHT/UVic./H. Hoekstra et al.)

Unit Conversion and Dimensional Analysis

It is often necessary to convert from one type of unit to another. For example, if you are reading a European cookbook, some quantities may be expressed in units of liters, and you need to convert them to cups. Or, perhaps you are reading walking directions from one location to another and you are interested in how many miles you will be walking. In this case, you will need to convert units of feet to miles.

Let us consider a simple example of how to convert units. Let us say that we want to convert 80 meters (m) to kilometers (km).

The first thing to do is to list the units that you have and the units that you want to convert to. In this case, we have units in **meters** and we want to convert to **kilometers**.

Next, we need to determine a **conversion factor** relating meters to kilometers. A conversion factor is a ratio expressing how many of one unit are equal to another unit. For example, there are 12 inches in 1 foot, 100 centimeters in 1 meter, 60 seconds in 1 minute, and so on. In this case, we know that there are 1 000 meters in 1 kilometer.

Now we can set up our unit conversion. We will write the units that we have and then multiply them by the conversion factor so that the units cancel out, as shown:

$$80\text{m} \times \frac{1\text{km}}{1000\text{m}} = 0.080\text{km}.$$

Note that the unwanted m unit cancels, leaving only the desired km unit. You can use this method to convert between any types of unit.

The [Appendix](#) has a more complete list of conversion factors.

Table 3: Approximate Values of Length, Mass, and Time

Lengths in meters	Masses in kilograms (more precise values in parentheses)	Times in seconds (more precise values in parentheses)
10^{-18} Present experimental limit to smallest observable detail	10^{-30} Mass of an electron (9.11×10^{-31} kg)	10^{-23} Time for light to cross a proton
10^{-15} Diameter of a proton	10^{-27} Mass of a hydrogen atom (1.67×10^{-27} kg)	10^{-22} Mean life of an extremely unstable nucleus
10^{-14} Diameter of a uranium nucleus	10^{-15} Mass of a bacterium	10^{-15} Time for one oscillation of visible light
10^{-10} Diameter of a hydrogen atom	10^{-5} Mass of a mosquito	10^{-13} Time for one vibration of an atom in a solid
10^{-8} Thickness of membranes in cells of living organisms	10^{-2} Mass of a hummingbird	10^{-8} Time for one oscillation of an FM radio wave
10^{-6} Wavelength of visible light	1 Mass of a liter of water (about a quart)	10^{-3} Duration of a nerve impulse
10^{-3} Size of a grain of sand	10^2 Mass of a person	1 Time for one heartbeat
1 Height of a 4-year-old child	10^3 Mass of a car	10^5 One day (8.64×10^4 s)

Lengths in meters		Masses in kilograms (more precise values in parentheses)		Times in seconds (more precise values in parentheses)	
10^2	Length of a football field	10^8	Mass of a large ship	10^7	One year (y) (3.16×10^7 s)
10^4	Greatest ocean depth	10^{12}	Mass of a large iceberg	10^9	About half the life expectancy of a human
10^7	Diameter of the Earth	10^{15}	Mass of the nucleus of a comet	10^{11}	Recorded history
10^{11}	Distance from the Earth to the Sun	10^{23}	Mass of the Moon (7.35×10^{22} kg)	10^{17}	Age of the Earth
10^{16}	Distance traveled by light in 1 year (a light year)	10^{25}	Mass of the Earth (5.97×10^{24} kg)	10^{18}	Age of the universe
10^{21}	Diameter of the Milky Way galaxy	10^{30}	Mass of the Sun (1.99×10^{30} kg)		
10^{22}	Distance from the Earth to the nearest large galaxy (Andromeda)	10^{42}	Mass of the Milky Way galaxy (current upper limit)		
10^{26}	Distance from the Earth to the edges of the known universe	10^{53}	Mass of the known universe (current upper limit)		

Unit Conversions: A Short Drive Home

Suppose that you drive the 10.0 km from your university to home in 20.0 min. Calculate your average speed (a) in kilometers per hour (km/h) and (b) in meters per second (m/s). (Note: Average speed is distance traveled divided by time of travel.)

Strategy

First we calculate the average speed using the given units. Then we can get the average speed into the desired units by picking the correct conversion factor and multiplying by it. The correct conversion factor is the one that cancels the unwanted unit and leaves the desired unit in its place.

Solution for (a)

(1) Calculate average speed. Average speed is distance traveled divided by time of travel. (Take this definition as a given for now—average speed and other motion concepts will be covered in a later module.) In equation form,

average speed = $\frac{\text{distance}}{\text{time}}$.

(2) Substitute the given values for distance and time.

average speed = $\frac{10.0 \text{ km}}{20.0 \text{ min}} = 0.500 \text{ km/min}$.

(3) Convert km/min to km/h: multiply by the conversion factor that will cancel minutes and leave hours. That conversion factor is 60 min/hr . Thus,

average speed = $0.500 \text{ km/min} \times 60 \frac{\text{min}}{1 \text{ h}} = 30.0 \text{ km/h}$.

Discussion for (a)

To check your answer, consider the following:

(1) Be sure that you have properly cancelled the units in the unit conversion. If you have written the unit conversion factor upside down, the units will not cancel properly in the equation. If you accidentally get the ratio upside down, then the units will not cancel; rather, they will give you the wrong units as follows:

$$\text{km/min} \times 1 \text{ hr} 60 \text{ min} = 160 \text{ km} \cdot \text{hr min}^2,$$

which are obviously not the desired units of km/h.

(2) Check that the units of the final answer are the desired units. The problem asked us to solve for average speed in units of km/h and we have indeed obtained these units.

(3) Check the significant figures. Because each of the values given in the problem has three significant figures, the answer should also have three significant figures. The answer 30.0 km/hr does indeed have three significant figures, so this is appropriate. Note that the significant figures in the conversion factor are not relevant because an hour is *defined* to be 60 minutes, so the precision of the conversion factor is perfect.

(4) Next, check whether the answer is reasonable. Let us consider some information from the problem—if you travel 10 km in a third of an hour (20 min), you would travel three times that far in an hour. The answer does seem reasonable.

Solution for (b)

There are several ways to convert the average speed into meters per second.

(1) Start with the answer to (a) and convert km/h to m/s. Two conversion factors are needed—one to convert hours to seconds, and another to convert kilometers to meters.

(2) Multiplying by these yields

$$\text{Average speed} = 30.0 \text{ km/h} \times 1 \text{ h} 3600 \text{ s} \times 1000 \text{ m} 1 \text{ km},$$

$$\text{Average speed} = 8.33 \text{ m/s}.$$

Discussion for (b)

If we had started with 0.500 km/min, we would have needed different conversion factors, but the answer would have been the same: 8.33 m/s.

You may have noted that the answers in the worked example just covered were given to three digits. Why? When do you need to be concerned about the number of digits in something you calculate? Why not write down all the digits your calculator produces? The module [Accuracy, Precision, and Significant Figures](#) will help you answer these questions.

Nonstandard Units

While there are numerous types of units that we are all familiar with, there are others that are much more obscure. For example, a **firkin** is a unit of volume that was once used to measure beer. One firkin equals about 34 liters. To learn more about nonstandard units, use a dictionary or encyclopedia to research different “weights and measures.” Take note of any unusual units, such as a barleycorn, that are not listed in the text. Think about how the unit is defined and state its relationship to SI units.

Check Your Understanding

Some hummingbirds beat their wings more than 50 times per second. A scientist is measuring the time it takes for a hummingbird to beat its wings once. Which fundamental unit should the scientist use to describe the measurement? Which factor of 10 is the scientist likely to use to describe the motion precisely? Identify the metric prefix that corresponds to this factor of 10.

Show Solution

The scientist will measure the time between each movement using the fundamental unit of seconds. Because the wings beat so fast, the scientist will probably need to measure in milliseconds, or 10^{-3} seconds. (50 beats per second corresponds to 20 milliseconds per beat.)

Check Your Understanding

One cubic centimeter is equal to one milliliter. What does this tell you about the different units in the SI metric system?

Show Solution

The fundamental unit of length (meter) is probably used to create the derived unit of volume (liter). The measure of a milliliter is dependent on the measure of a centimeter.

Summary

- Physical quantities are a characteristic or property of an object that can be measured or calculated from other measurements.
- Units are standards for expressing and comparing the measurement of physical quantities. All units can be expressed as combinations of four fundamental units.
- The four fundamental units we will use in this text are the meter (for length), the kilogram (for mass), the second (for time), and the ampere (for electric current). These units are part of the metric system, which uses powers of 10 to relate quantities over the vast ranges encountered in nature.
- The four fundamental units are abbreviated as follows: meter, m; kilogram, kg; second, s; and ampere, A. The metric system also uses a standard set of prefixes to denote each order of magnitude greater than or lesser than the fundamental unit itself.
- Unit conversions involve changing a value expressed in one type of unit to another type of unit. This is done by using conversion factors, which are ratios relating equal quantities of different units.

Conceptual Questions

Identify some advantages of metric units.

Problems & Exercises

The speed limit on some interstate highways is roughly 100 km/h. (a) What is this in meters per second? (b) How many miles per hour is this?

Show Solution

Strategy

Use conversion factors to convert between units. Remember: 1 km = 1000 m, 1 hour = 3600 s, and 1 km = 0.6214 miles.

Solution

(a) Convert 100 km/h to m/s:

$$100 \text{ km/h} \times \frac{1000 \text{ m}}{1 \text{ km}} \times \frac{1 \text{ h}}{3600 \text{ s}} = 100 \times \frac{1000}{3600} \text{ m/s} = 27.8 \text{ m/s}$$

(b) Convert 100 km/h to miles per hour:

$$100 \text{ km/h} \times 0.6214 \text{ mi/km} = 62.1 \text{ mph}$$

Discussion

The conversion from km/h to m/s requires two conversion factors that work together to change both the distance and time units. The result of 27.8 m/s means the car travels about 28 meters in one second, which is reasonable for highway speeds. Both answers maintain three significant figures, matching the precision of the original measurement of 100 km/h.

Answer

(a) 27.8m/s

(b) 62.1mph

A car is traveling at a speed of 33m/s. (a) What is its speed in kilometers per hour? (b) Is it exceeding the 90km/h speed limit?

Show Solution

Strategy

Convert the speed from m/s to km/h using appropriate conversion factors, then compare with the speed limit.

Solution

(a) Convert 33 m/s to km/h:

$$33\text{m/s} \times 1 \frac{\text{km}}{1000\text{m}} \times 3600\frac{\text{s}}{1\text{h}} = 33 \times 3600 \frac{1}{1000} \text{km/h} = 119 \text{ km/h}$$

Alternatively, using the conversion factor from Problem 3: 1.0 m/s = 3.6 km/h:

$$33\text{m/s} \times 3.6 = 119 \text{ km/h} \approx 120 \text{ km/h}$$

(b) Comparison with speed limit:

Since 119 km/h > 90 km/h, yes, the car is exceeding the speed limit by 29 km/h.

Discussion

This problem demonstrates the utility of the conversion factor 1.0 m/s = 3.6 km/h, which is commonly used in physics. The car's speed of 119 km/h is significantly over the 90 km/h limit, exceeding it by about 32%. This speed of 33 m/s means the car travels the length of a basketball court in less than one second, which helps put the speed in perspective.

Answer

(a) The car's speed is **120 km/h** (or 119 km/h to three significant figures).

(b) Yes, the car is exceeding the 90 km/h speed limit.

Show that 1.0m/s = 3.6km/h. Hint: Show the explicit steps involved in converting 1.0m/s = 3.6km/h.

Show Solution

$$1.0\text{m/s} = 1.0\text{m/s} \times 3600\frac{\text{s}}{1\text{hr}} \times 1\frac{\text{km}}{1000\text{m}} = 3.6\text{km/h.}$$

Discussion

This conversion factor is particularly useful because it relates the SI unit of speed (m/s) to the more common everyday unit of km/h. The factor of 3.6 arises from the combination of 3600 seconds per hour and 1000 meters per kilometer (3600/1000 = 3.6). Memorizing this simple relationship allows for quick mental conversions between these common speed units.

American football is played on a 100-yd-long field, excluding the end zones. How long is the field in meters? (Assume that 1 meter equals 3.281 feet.)

Show Solution

Strategy

Convert from yards to feet, then from feet to meters using the given conversion factor.

Solution

1. Convert yards to feet (1 yard = 3 feet):

$$100 \text{ yd} \times 3 \frac{\text{ft}}{1 \text{ yd}} = 300 \text{ ft}$$

1. Convert feet to meters (1 m = 3.281 ft):

$$300 \text{ ft} \times 1\text{m} \frac{1}{3.281 \text{ ft}} = 91.4\text{m}$$

Discussion

The result shows that an American football field is slightly less than 100 meters long, which provides a useful reference point for estimating distances. The conversion required using two factors: first yards to feet (3 ft/yd), then feet to meters. The answer of 91.4 m is given to three significant figures, matching the precision of the original 100-yard measurement.

Answer

The football field is **91.4 m** long.

Soccer fields vary in size. A large soccer field is 115 m long and 85 m wide. What are its dimensions in feet and inches? (Assume that 1 meter equals 3.281 feet.)

Show Solution

Strategy

Convert from meters to feet using the conversion factor $1 \text{ m} = 3.281 \text{ ft}$, then convert feet to inches using $1 \text{ ft} = 12 \text{ in.}$

Solution

Length (115 m):

$$115 \text{ m} \times 3.281 \text{ ft/m} = 377 \text{ ft}$$

$$377 \text{ ft} \times 12 \text{ in./ft} = 4.53 \times 10^3 \text{ in.}$$

Width (85 m):

$$85 \text{ m} \times 3.281 \text{ ft/m} = 279 \text{ ft} \approx 280 \text{ ft}$$

$$280 \text{ ft} \times 12 \text{ in./ft} = 3.3 \times 10^3 \text{ in.}$$

Discussion

The soccer field dimensions in feet (377 ft by 280 ft) show that it is larger than an American football field in both length and width. Using scientific notation for the inch measurements ($4.53 \times 10^3 \text{ in.}$ and $3.3 \times 10^3 \text{ in.}$) is appropriate because these are large numbers that would be cumbersome to write out. The significant figures reflect the precision of the original metric measurements, with the width rounded to two significant figures based on the value 85 m.

Answer

Length: 377ft; $4.53 \times 10^3 \text{ in.}$

Width: 280ft; $3.3 \times 10^3 \text{ in.}$

What is the height in meters of a person who is 6 ft 1.0 in. tall? (Assume that 1 meter equals 39.37 in.)

Show Solution

Strategy

First convert the total height to inches, then convert to meters using the given conversion factor.

Solution

1. Convert 6 ft 1.0 in. to total inches:

$$6 \text{ ft} \times 12 \text{ in./ft} + 1.0 \text{ in.} = 72 \text{ in.} + 1.0 \text{ in.} = 73.0 \text{ in.}$$

1. Convert inches to meters ($1 \text{ m} = 39.37 \text{ in.}$):

$$73.0 \text{ in.} \times 1 \text{ m} / 39.37 \text{ in.} = 1.85 \text{ m}$$

Discussion

A height of 1.85 m (or 185 cm) is reasonable for a person who is 6 ft 1 in. tall, representing a height above average for most populations. The conversion from English units to SI units demonstrates the importance of first combining mixed units (feet and inches) into a single unit before converting. The result is given to three significant figures, consistent with the precision of the original measurement.

Answer

The person's height is **1.85 m**.

Mount Everest, at 29 028 feet, is the tallest mountain on the Earth. What is its height in kilometers? (Assume that 1 kilometer equals 3 281 feet.)

Show Solution

Strategy

Convert from feet to kilometers using the given conversion factor: $1 \text{ km} = 3281 \text{ ft}$.

Solution

$$29028 \text{ ft} \times 1 \text{ km} / 3281 \text{ ft} = 8.847 \text{ km}$$

Discussion

Mount Everest's height of approximately 8.8 km helps put the mountain's scale into perspective—it reaches nearly 9 kilometers into the atmosphere. This height is significant because it places the summit in the “death zone” where atmospheric pressure is only about one-third that at sea level. The precision to four significant figures (8.847 km) reflects the accuracy of modern surveying techniques used to measure this iconic peak.

Answer

8.847km

The speed of sound is measured to be 342m/s on a certain day. What is this in km/h?

Show Solution

Strategy

Convert the speed from m/s to km/h using the conversion factors: 1 km = 1000 m and 1 h = 3600 s.

Solution

$$342\text{m/s} \times 1\text{ km}/1000\text{m} \times 3600\text{s}/1\text{ h} = 342 \times 3600/1000\text{km/h} = 1231\text{ km/h} \approx 1230\text{ km/h}$$

Alternatively, using the conversion 1.0 m/s = 3.6 km/h:

$$342\text{m/s} \times 3.6 = 1231\text{ km/h} \approx 1.23 \times 10^3\text{ km/h}$$

Discussion

The speed of sound at approximately 1230 km/h is much faster than typical highway speeds (around 100 km/h) but still much slower than the speed of light. This value varies with temperature and atmospheric conditions, which is why the problem states it was “measured on a certain day.” Expressing the answer with three significant figures (1230 km/h or $1.23 \times 10^3\text{ km/h}$) properly reflects the precision of the original measurement of 342 m/s.

Answer

The speed of sound is **1230 km/h** (or **$1.23 \times 10^3\text{ km/h}$** in scientific notation).

Tectonic plates are large segments of the Earth's crust that move slowly. Suppose that one such plate has an average speed of 4.0 cm/year. (a) What distance does it move in 1 s at this speed? (b) What is its speed in kilometers per million years?

Show Solution

Strategy

Convert the speed of 4.0 cm/year to the requested units using appropriate conversion factors.

Solution**(a) Distance moved in 1 second:**

First convert 4.0 cm/year to meters per second:

$$4.0\text{cm/year} \times 1\text{m}/100\text{ cm} \times 1\text{ year}/365\text{ days} \times 1\text{ day}/24\text{ h} \times 1\text{ h}/3600\text{s} \\ = 4.0/100 \times 365 \times 24 \times 3600\text{ms} = 1.27 \times 10^{-9}\text{ms} \approx 1.3 \times 10^{-9}\text{ms}$$

In 1 second, the plate moves: $1.3 \times 10^{-9}\text{m}$

(b) Speed in km per million years:

$$4.0\text{cm/year} \times 1\text{m}/100\text{ cm} \times 1\text{ km}/1000\text{m} \times 10^6\text{ years}/1\text{ My} \\ = 4.0 \times 10^6/100 \times 1000\text{kmMy} = 40\text{kmMy}$$

Discussion

The extremely small distance of $1.3 \times 10^{-9}\text{ m}$ per second illustrates why tectonic motion is imperceptible in everyday life—this is about one nanometer per second, roughly the size of a few atoms. However, over geological time scales of millions of years, this slow movement accumulates to 40 km per million years, which is significant enough to create mountains and move continents. This problem demonstrates the importance of choosing appropriate time scales when describing processes that occur at vastly different rates.

Answer

(a) $1.3 \times 10^{-9}\text{m}$

(b) 40km/My

(a) Refer to [Table 3](#) to determine the average distance between the Earth and the Sun. Then calculate the average speed of the Earth in its orbit in kilometers per second. (b) What is this in meters per second?

Show Solution

Strategy

From Table 3, find the Earth-Sun distance. Calculate the circumference of Earth's orbit, divide by the time for one orbit (1 year), then convert to the requested units.

Solution

1. From Table 3, the distance from Earth to Sun is approximately 10^{11}m (more precisely, about $1.5 \times 10^{11}\text{m}$).
2. The circumference of Earth's orbit (assuming circular):

$$C = 2\pi r = 2\pi(1.5 \times 10^{11}\text{m}) = 9.42 \times 10^{11}\text{m}$$

1. Time for one orbit is 1 year. From Table 3, one year = $3.16 \times 10^7\text{s}$.

(a) Speed in km/s:

$$v = C/t = 9.42 \times 10^{11}\text{m} / 3.16 \times 10^7\text{s} = 2.98 \times 10^4\text{m/s}$$

Convert to km/s:

$$v = 2.98 \times 10^4\text{m/s} \times \frac{1\text{ km}}{1000\text{m}} = 29.8\text{ km/s} \approx 30\text{ km/s}$$

(b) Speed in m/s:

$$\text{From above: } v = 2.98 \times 10^4\text{m/s} \approx 3.0 \times 10^4\text{m/s}$$

Discussion

Earth's orbital speed of approximately 30 km/s (or 30,000 m/s) is remarkably fast—about 108,000 km/h—yet we don't feel this motion because we're moving along with the Earth. This speed is much greater than the speed of sound (about 0.34 km/s) and represents the velocity needed to maintain a stable orbit around the Sun at Earth's distance. The calculation assumes a circular orbit, which is a good approximation since Earth's orbit is nearly circular with an eccentricity of only 0.017.

Answer

- (a) The average speed of Earth in its orbit is approximately **30 km/s**.
 (b) This is approximately **$3.0 \times 10^4\text{ m/s}$** (or 30,000 m/s).

Glossary

physical quantity

a characteristic or property of an object that can be measured or calculated from other measurements

units

a standard used for expressing and comparing measurements

SI units

the international system of units that scientists in most countries have agreed to use; includes units such as meters, liters, and grams

English units

system of measurement used in the United States; includes units of measurement such as feet, gallons, and pounds

fundamental units

units that can only be expressed relative to the procedure used to measure them

derived units

units that can be calculated using algebraic combinations of the fundamental units

second

the SI unit for time, abbreviated (s)

meter

the SI unit for length, abbreviated (m)

kilogram

the SI unit for mass, abbreviated (kg)

metric system

a system in which values can be calculated in factors of 10

order of magnitude

refers to the size of a quantity as it relates to a power of 10

conversion factor

a ratio expressing how many of one unit are equal to another unit

Approximation

- Make reasonable approximations based on given data.

On many occasions, physicists, other scientists, and engineers need to make **approximations** or “guesstimates” for a particular quantity. What is the distance to a certain destination? What is the approximate density of a given item? About how large a current will there be in a circuit? Many approximate numbers are based on formulae in which the input quantities are known only to a limited accuracy. As you develop problem-solving skills (that can be applied to a variety of fields through a study of physics), you will also develop skills at approximating. You will develop these skills through thinking more quantitatively, and by being willing to take risks. As with any endeavor, experience helps, as well as familiarity with units. These approximations allow us to rule out certain scenarios or unrealistic numbers. Approximations also allow us to challenge others and guide us in our approaches to our scientific world. Let us do two examples to illustrate this concept.

Approximate the Height of a Building

Can you approximate the height of one of the buildings on your campus, or in your neighborhood? Let us make an approximation based upon the height of a person. In this example, we will calculate the height of a 39-story building.

Strategy

Think about the average height of an adult male. We can approximate the height of the building by scaling up from the height of a person.

Solution

Based on information in the example, we know there are 39 stories in the building. If we use the fact that the height of one story is approximately equal to about the length of two adult humans (each human is about 2-m tall), then we can estimate the total height of the building to be

$$2\text{m/person} \times 2\text{person/1story} \times 39\text{stories} = 156\text{m}.$$

Discussion

You can use known quantities to determine an approximate measurement of unknown quantities. If your hand measures 10 cm across, how many hand lengths equal the width of your desk? What other measurements can you approximate besides length?

Approximating Vast Numbers: a Trillion Dollars

A bank stack contains one-hundred \$100 bills, and is worth \$10 000. How many bank stacks make up a trillion dollars? (credit: Andrew Magill)

The U.S. federal deficit in the 2019 fiscal year was a little greater than 1 trillion. Most of us do not have any concept of how much even one trillion actually is. Suppose that you were given a trillion dollars in \$100 bills. If you made 100-bill stacks and used them to evenly cover a football field (between the end zones), make an approximation of how high the money pile would become. (We will use feet/inches rather than meters here because football fields are measured in yards.) One of your friends says 3 in., while another says 10 ft. What do you think?

Strategy

When you imagine the situation, you probably envision thousands of small stacks of 100 wrapped \$100 bills, such as you might see in movies or at a bank. Since this is an easy-to-approximate quantity, let us start there. We can find the volume of a stack of 100 bills, find out how many stacks make up one trillion dollars, and then set this volume equal to the area of the football field multiplied by the unknown height.

Solution

(1) Calculate the volume of a stack of 100 bills. The dimensions of a single bill are approximately 3 in. by 6 in. A stack of 100 of these is about 0.5 in. thick. So the total volume of a stack of 100 bills is:

$$\text{volume of stack} = \text{length} \times \text{width} \times \text{height}, \quad \text{volume of stack} = 6\text{in.} \times 3\text{in.} \times 0.5\text{in.}, \quad \text{volume of stack} = 9\text{in.}^3.$$

(2) Calculate the number of stacks. Note that a trillion dollars is equal to $\$1 \times 10^{12}$, and a stack of one-hundred 100 bills is equal to 10 000, or $\$1 \times 10^4$. The number of stacks you will have is:

$$\$1 \times 10^{12} \text{ (a trillion dollars)} \div \$10^4 \text{ per stack} = 1 \times 10^8 \text{ stacks.}$$

(3) Calculate the area of a football field in square inches. The area of a football field is $100\text{yd} \times 50\text{yd}$, which gives 5000yd^2 . Because we are working in inches, we need to convert square yards to square inches:

$$\text{Area} = 5000\text{yd}^2 \times 3\text{ft} \times 1\text{yd} \times 3\text{ft} \times 12\text{in.} \times 12\text{in.} = 6480000\text{in.}^2, \quad \text{Area} \approx 6 \times 10^6\text{in.}^2.$$

This conversion gives us $6 \times 10^6\text{in.}^2$ for the area of the field. (Note that we are using only one significant figure in these calculations.)

(4) Calculate the total volume of the bills. The volume of all the \$100 -bill stacks is $9\text{in.}^3/\text{stack} \times 10^8 \text{ stacks} = 9 \times 10^8\text{in.}^3$. (5) Calculate the height. To determine the height of the bills, use the equation:

$$\begin{aligned} \text{volume of bills} &= \text{area of field} \times \text{height of money:} & \text{Height of money} &= \frac{\text{volume of bills}}{\text{area of field}}, & \text{Height of} \\ \text{money} &= \frac{9 \times 10^8\text{in.}^3}{6 \times 10^6\text{in.}^2} = 1.33 \times 10^2\text{in.}, & \text{Height of money} &\approx 1 \times 10^2\text{in.} = 100\text{in.} \end{aligned}$$

The height of the money will be about 100 in. high. Converting this value to feet gives

$$100\text{in.} \times \frac{1\text{ft}}{12\text{in.}} = 8.33\text{ft} \approx 8\text{ft.}$$

Discussion

The final approximate value is much higher than the early estimate of 3 in., but the other early estimate of 10 ft (120 in.) was roughly correct. How did the approximation measure up to your first guess? What can this exercise tell you in terms of rough “guesstimates” versus carefully calculated approximations?

Check Your Understanding

Using mental math and your understanding of fundamental units, approximate the area of a regulation basketball court. Describe the process you used to arrive at your final approximation.

Show Solution

An average male is about two meters tall. It would take approximately 15 men laid out end to end to cover the length, and about 7 to cover the width. That gives an approximate area of 420m^2 .

Summary

Scientists often approximate the values of quantities to perform calculations and analyze systems.

Problems & Exercises

How many heartbeats are there in a lifetime?

Show Solution

Strategy

To estimate heartbeats in a lifetime, we need to estimate the average heart rate and average lifespan.

Solution

1. Estimate average heart rate: approximately 70 beats per minute (at rest, it varies but this is a reasonable average including sleep and activity).
2. Estimate average lifespan: approximately 80 years.
3. Calculate minutes in a lifetime:

$$80 \text{ years} \times 365 \text{ days} \times 1 \text{ year} \times 24 \text{ hours} \times 1 \text{ day} \times 60 \text{ min} \times 1 \text{ hour} \approx 4.2 \times 10^7 \text{ minutes}$$

1. Calculate total heartbeats:

$$70 \text{ beats/min} \times 4.2 \times 10^7 \text{ min} \approx 3 \times 10^9 \text{ heartbeats}$$

Discussion

This enormous number of approximately 3 billion heartbeats illustrates the remarkable endurance and reliability of the human heart as a muscle that never rests. The calculation assumes a relatively constant average heart rate of 70 bpm, though actual heart rates vary significantly with activity level, age, and health status. This order-of-magnitude estimate helps us appreciate the incredible workload the cardiovascular system handles over a lifetime, beating roughly once per second for 80 years without pause.

Sample answer: 2×10^9 to 3×10^9 heartbeats

A generation is about one-third of a lifetime. Approximately how many generations have passed since the year 0 AD?

Show Solution

Strategy

Estimate the time since year 0 AD, then divide by the length of a generation.

Solution

1. Time since year 0 AD to present (2025):

Time elapsed ≈ 2025 years ≈ 2000 years

1. If a generation is about one-third of a lifetime, and an average lifetime is about 70-80 years:

Generation length ≈ 70 years ≈ 25 years

1. Number of generations:

Number of generations = $2000 \text{ years} / 25 \text{ years/generation} = 80$ generations

Discussion

The relatively small number of only 80 generations shows how recent human recorded history is when viewed from a biological perspective. This calculation assumes a generation length of approximately 25 years, though this value has varied significantly across different cultures, time periods, and socioeconomic conditions. Understanding this timescale is valuable for studying genetic inheritance, cultural transmission of knowledge, and the relatively rapid pace of human cultural evolution compared to biological evolution.

Answer

Approximately **80 generations** have passed since the year 0 AD (assuming about 25 years per generation).

How many times longer than the mean life of an extremely unstable atomic nucleus is the lifetime of a human? (Hint: The lifetime of an unstable atomic nucleus is on the order of 10^{-22} s.)

Show Solution

Strategy

We need to compare the human lifetime to the lifetime of an unstable atomic nucleus by finding their ratio.

Solution

1. From the hint, the lifetime of an unstable atomic nucleus is on the order of 10^{-22} s.
2. Convert human lifetime to seconds. Assuming an average human lifetime of about 70 years:

$70 \text{ years} \times 365 \text{ days} / 1 \text{ year} \times 24 \text{ hours} / 1 \text{ day} \times 3600 \text{ s} / 1 \text{ hour} \approx 2.2 \times 10^9 \text{ s}$

1. Calculate the ratio:

Human lifetime / Nucleus lifetime = $2.2 \times 10^9 \text{ s} / 10^{-22} \text{ s} \approx 2 \times 10^{31}$

Discussion

This truly astronomical factor of 10^{31} illustrates the vast range of timescales that exist in nature, from quantum processes to human experience. To put this in perspective, a human lifetime is longer than a nuclear decay timescale by the same factor that the age of the universe is longer than a fraction of a second. This extreme comparison demonstrates both the power of scientific notation in handling such disparate scales and helps us appreciate how quantum phenomena occur on timescales completely outside our everyday intuition.

Sample answer: 2×10^{31} times longer (if an average human lifetime is taken to be about 70 years).

Calculate the approximate number of atoms in a bacterium. Assume that the average mass of an atom in the bacterium is ten times the mass of a hydrogen atom. (Hint: The mass of a hydrogen atom is on the order of 10^{-27} kg and the mass of a bacterium is on the order of 10^{-15} kg).

Show Solution

Strategy

Divide the total mass of the bacterium by the average mass of an atom to find the number of atoms.

Solution

1. From the hint:

- Mass of hydrogen atom: $m_H \approx 10^{-27} \text{ kg}$
- Mass of bacterium: $m_{bact} \approx 10^{-15} \text{ kg}$

2. Average mass of an atom in the bacterium:

$$m_{atom} = 10 \times m_H = 10 \times 10^{-27} \text{ kg} = 10^{-26} \text{ kg}$$

1. Number of atoms:

$$N = m_{bact} / m_{atom} = 10^{-15} \text{ kg} / 10^{-26} \text{ kg} = 10^{11} \text{ atoms}$$

Discussion

The result of approximately 100 billion atoms reveals that even the tiniest living organisms contain an enormous number of atoms, providing ample complexity for the molecular machinery of life. This calculation assumes all atoms in the bacterium have an average mass of 10 times that of hydrogen, which is reasonable given that bacteria contain heavier atoms like carbon, nitrogen, and oxygen in addition to hydrogen. This order-of-magnitude estimate helps us understand why even single-celled organisms can have sophisticated metabolic pathways and genetic information storage despite their microscopic size.

Answer

A bacterium contains approximately **10^{11} atoms** (or about 100 billion atoms).

This color-enhanced photo shows *Salmonella typhimurium* (red) attacking human cells. These bacteria are commonly known for causing foodborne illness. Can you estimate the number of atoms in each bacterium? (credit: Rocky Mountain Laboratories, NIAID, NIH)

Approximately how many atoms thick is a cell membrane, assuming all atoms there average about twice the size of a hydrogen atom?

Show Solution

Strategy

We need to estimate how many atoms fit across the thickness of a cell membrane, given that the atoms are about twice the size of a hydrogen atom.

Solution

1. A typical cell membrane thickness is approximately 10^{-8} m (or about 10 nm).
2. The diameter of a hydrogen atom is approximately 10^{-10} m (or about 0.1 nm).
3. If atoms in the membrane average about twice the size of a hydrogen atom:

$$\text{Average atom diameter} \approx 2 \times 10^{-10} \text{ m}$$

1. Calculate the number of atoms across the membrane thickness:

$$\text{Number of atoms} = \text{Membrane thickness} / \text{Atom diameter} = 10^{-8} \text{ m} / 2 \times 10^{-10} \text{ m} = 50 \text{ atoms}$$

Discussion

The remarkably small thickness of only about 50 atoms demonstrates how incredibly thin cell membranes are, yet they successfully maintain the cell's integrity and control what enters and exits. This estimate assumes atoms in the membrane are roughly uniform in size at about twice the hydrogen atom diameter, which is reasonable for the lipid and protein molecules that make up biological membranes. The fact that such a thin barrier can effectively

separate the cell's interior from its environment while still allowing selective transport of materials is one of the elegant solutions nature has evolved for cellular function.

Sample answer: 50 atoms

(a) What fraction of Earth's diameter is the greatest ocean depth? (b) The greatest mountain height?

Show Solution

Strategy

Use Table 3 to find the relevant values, then calculate the ratios.

Solution

From Table 3:

- Diameter of Earth: $d_{Earth} = 10^7 \text{ m}$ (more precisely, about $1.27 \times 10^7 \text{ m}$)
- Greatest ocean depth: $d_{ocean} = 10^4 \text{ m}$ (about 10,000 m, or the Mariana Trench at $\sim 11,000 \text{ m}$)
- Greatest mountain height: $h_{mountain} = 10^4 \text{ m}$ (Mt. Everest is about 8,850 m)

(a) Fraction for ocean depth:

$$\text{Fraction} = \frac{d_{ocean}}{d_{Earth}} = \frac{10^4 \text{ m}}{10^7 \text{ m}} = 10^{-3} = 1/1000$$

(b) Fraction for mountain height:

$$\text{Fraction} = \frac{h_{mountain}}{d_{Earth}} = \frac{10^4 \text{ m}}{10^7 \text{ m}} = 10^{-3} = 1/1000$$

Discussion

The tiny ratio of 1/1000 for both ocean depths and mountain heights reveals that Earth is remarkably smooth relative to its overall size—the deepest trenches and highest peaks represent only about 0.1% of Earth's diameter. This explains why our planet appears as a smooth sphere when viewed from space, with surface irregularities barely visible. To put this in perspective, if Earth were shrunk to the size of a billiard ball, it would actually be smoother than a regulation billiard ball, since these surface features would scale down proportionally.

Answer

(a) The greatest ocean depth is approximately **1/1000** (or **0.001** or 10^{-3}) of Earth's diameter.

(b) The greatest mountain height is approximately **1/1000** (or **0.001** or 10^{-3}) of Earth's diameter.

Both the deepest ocean trenches and highest mountains are tiny compared to Earth's diameter, representing only about 0.1% of it.

(a) Calculate the number of cells in a hummingbird assuming the mass of an average cell is ten times the mass of a bacterium. (b) Making the same assumption, how many cells are there in a human?

Show Solution

Strategy

We need to estimate the number of cells by dividing the total mass by the mass of a single cell (which is 10 times the mass of a bacterium).

Solution

1. From the problem, an average cell mass is ten times the mass of a bacterium. From Table 3, the mass of a bacterium is approximately 10^{-15} kg , so:

$$\text{Cell mass} \approx 10 \times 10^{-15} \text{ kg} = 10^{-14} \text{ kg}$$

(a) Cells in a hummingbird:

1. The mass of a hummingbird is approximately 10^{-2} kg (about 10 grams, or roughly 0.01 kg).
2. Calculate number of cells:

$$\text{Number of cells} = \frac{\text{Hummingbird mass}}{\text{Cell mass}} = \frac{10^{-2} \text{ kg}}{10^{-14} \text{ kg}} = 10^{12} \text{ cells}$$

(b) Cells in a human:

1. The mass of a human is approximately 10^2 kg (about 100 kg, though 70 kg is more typical).
2. Calculate number of cells:

$$\text{Number of cells} = \frac{\text{Human mass}}{\text{Cell mass}} = \frac{10^2 \text{ kg}}{10^{-14} \text{ kg}} = 10^{16} \text{ cells}$$

Discussion

The ratio of approximately 10,000:1 in cell count between humans and hummingbirds roughly corresponds to the ratio of their masses, which is reasonable given our assumption of uniform cell size. In reality, cell sizes vary dramatically across different tissue types (neurons, blood cells, muscle cells all differ), but this order-of-magnitude approximation remains useful for understanding biological scale. These enormous numbers—trillions for a hummingbird and ten quadrillion for a human—illustrate the incredible cellular complexity that underlies even small multicellular organisms.

Sample answers:

(a) 10^{12} cells/hummingbird

(b) 10^{16} cells/human

Assuming one nerve impulse must end before another can begin, what is the maximum firing rate of a nerve in impulses per second?

Show Solution

Strategy

From Table 3, find the duration of a nerve impulse, then calculate the maximum firing rate.

Solution

1. From Table 3, the duration of a nerve impulse is approximately 10^{-3} s (or 1 millisecond).
2. If one impulse must complete before another begins, the maximum firing rate is:

$$\text{Firing rate} = \frac{1}{\text{Duration}} = \frac{1}{10^{-3} \text{ s}} = 10^3 \text{ impulses/s} = 1000 \text{ Hz}$$

Discussion

A maximum firing rate of 1000 Hz (1000 impulses per second) represents the theoretical upper limit based on the refractory period during which a neuron cannot fire again. This calculation assumes that impulses cannot overlap and that the neuron fires immediately after each refractory period ends, which represents an idealized maximum. In biological reality, most neurons fire at rates well below this limit—typically a few hundred Hz at most—because sustained high-frequency firing would be metabolically expensive and is usually unnecessary for neural signaling.

Answer

The maximum firing rate of a nerve is approximately **1000 impulses per second** (or **1000 Hz**, or **10^3 Hz**).

This is consistent with known biological limits - most neurons fire at rates well below 1000 Hz, with typical maximum rates being a few hundred Hz for most neurons.
